

School of Computer Engineering and Technology

Subject: Artificial Intelligence and ML Techniques

Program: B.Tech. - CSF

Class: T.Y.

Date of assignment: 11th Sept 2023Date of Submission: 25th Sept 2023

1. Explain the classification of environments in detail and explain PEAS analysis for automated taxi agent. [5 marks]
2. Derive 3 different heuristic functions to solve 8 puzzle problem and Explain admissibility property of A* algorithm in detail. [5 marks]
3. Explain the Minimax Algorithm with Alpha-beta pruning. [5 Marks]
4. Explain Local Search Algorithm. Solve travelling salesman problem using local search algorithm. [5 Marks]
5. Assume that the nodes are expanded in alphabetical order when no other order is specified by the search, and that the goal is state G. No visited or expanded lists are used. What order would the states be expanded by each type of search? Stop when you expand G. Write only the sequence of states expanded by each search (BFS, DFS, Uniform Cost Search). [5 Marks]

A I Theory assignment 1.

Q.1. Explain the classification of environment in detail and explain PEAS analysis for automated taxi agent.

→ Classification of Environment :

They can be classified based on several criteria including observability, determinism, episodic vs sequential, static vs dynamic, discrete vs. continuous and single agent vs multi agent.

A. Observability:

(i) Fully observable : An agent has access to the complete state of the environment at all times.

(ii) Partially observable : The agent has limited or partial access to the state of the environment.

B. Determinism:

1. Deterministic : The next state of the environment is completely determined by the current state; and the actions taken by the agent.

2. Stochastic : The next state is partially random or uncertain even with the same actions and current state.

C. Episodic vs. sequential :

- Episodic : The agent experience is divided into independent episodes and each episode does not depend on previous ones. 1.
- Sequential : The current decision and action may affect all future decisions and outcomes.

D. Static vs. Dynamic:

- Static : The env. does not change while an agent is deliberating.
- Dynamic : The environment may change while the agent is deciding on its actions. 3.

E. Discrete vs. Continuous

- Discrete : The states, actions or time are divided into distinct separate units. 4.
- Continuous : The states, actions or time are continuous and not divided into discrete units.

F. Single agent vs. Multi agent

- Single : There is only one agent interacting with the environment. 5.
- Multi-agent : Multiple agents interact with each other and the environment.

PEAS analysis for automated Taxi Agent:

1. Performance Agent Measure: Can be measured by metrics such as reaching the destination in the shortest time, providing a comfortable ride, adhering to traffic rules, minimizing fuel consumption, etc.
 2. Environment: It includes the road network, traffic conditions, weather, other vehicles, pedestrians, traffic signals, etc.
 3. Actuators: They include the vehicle's steering, accelerator, brake, turn signals, GPS navigation system, etc.
 4. Sensors: They include cameras, LIDAR, ultrasonic sensors, GPS, speedometers, traffic sensors, temperature sensors and microphones for understanding environment.
- Q. 2. Define 3 heuristic functions to solve 8 puzzle problem and explain admissibility property of a A* alg in detail.

→ Heuristic function estimates the cost from a given state to the goal state. These commonly used heuristics are:

1. Misplaced tiles: This heuristic calculates the number of tiles that are not in their

their goal position in the current state. It underestimates the true cost as it assumes that moving a tile to its goal position will not disturb other tiles.

2. Manhattan distance Heuristic : This calculates the

sum of the ~~no~~ manhattan distances of each slide tile from its current position to its goal position. The manhattan distance for a tile is the sum of the horizontal and vertical distances between the current position and the goal position.

3. Linear Conflict Heuristic

This heuristic extends the Manhattan distance heuristic by considering conflict between tiles in the same row or a column. It is admissible since it considers a lower bound on the actual cost by accounting for the conflicts.

Admissibility property of A* algorithm :-

→ Admissibility is crucial because it guarantees that A* will find an optimal solution.

→ A* uses the heuristic to guide its search, if the heuristic is admissible, A* is guaranteed to find the shortest path.

→ When the heuristic is admissible, A* explores the search space efficiently, prioritizing nodes that are likely to lead to optimal solutions, improving performance.

Admissibility Definition:

In an A* search, a heuristic $h(n)$ is admissible if and only if it never overestimates the true cost to reach the goal from only given state.

$$h(n) \leq h^*(n)$$

where $h^*(n)$ is the true (optimal) cost from state n to the goal.

③ Explain the minimax alg with $\alpha-\beta$ pruning.

→ Minimization and Maximization:

Maximizes aims to maximize ~~to~~ the score.

→ Recursion Tree Exploration (Game Tree):

The algorithm explores a game tree where each level alternates between max and min nodes.

(*) Terminal node evaluation:

At the leaf nodes (terminal states) the utility function evaluates the state of the game and provides a numerical value representing the outcome of the max player.

(*) Backward propagation:

The algorithm propagates the values back up the tree, updating the values for each of its children.

(*) Decision :

Finally, Max selects the move that leads to the highest value among its child nodes.

(*) Alpha Beta Pruning:

→ Alpha and Beta are the best value that the maximizing & minimizing player respectively can guarantee at or above the current level.

→ Pruning Condition: During the tree traversal if the algorithm finds a decision node's value that makes it irrelevant for further condition exploration, it prunes the subtree rooted at that node.

(*) Pruning Operation:

If the current node is a minimum node and its value is less than or equal to alpha, prune the subtree and set the value.

(*) Updating Alpha and Beta:

When traversing the tree, update alpha for min nodes as the maximum of alpha and the current node's value.

Q.4. Explain local search algorithm. solve Travelling salesmen problem using local search algorithm.

→ Initialization:

Start with an initial solution. Set the current solution as the initial solution.

→ Evaluation:

Evaluate the current solution to determine its quality based on the objective function or evaluation criteria.

→ Neighbours Generation:

generate neighbouring solutions by making small changes to the current solution.

(2) Selection:

→ Select the best neighbors based on evaluation criteria.

(3) Termination condition:

→ Repeat steps 3-9 until a stopping criteria is met.

(4) Output

Return the best solution found during search.

(5) TSP

Let's consider (A, B, C, D, E) as 5 cities and their pairwise distances.

- let us begin with an initial random tour

$$A \rightarrow B \rightarrow C \rightarrow D \rightarrow E \rightarrow A.$$

→ we apply the local search algorithm iteratively to improve the tour and minimize the total distance. After several iterations we'll reach a locally optimal tour with the shortest total distance

Q.5'

BFS:

Queue : A, B, C, D, E, G, H, F, I, J, K, L

So output which we have to stop at G

DFS

UCS

$g(n)$ = cost from start \rightarrow current node

A	$[B_1, C_2]$
B	$[D_2, E_2, C_3]$
D	$[E_2, F_3, C_2]$
E	$[F_3, C_3]$
C	$[F_3, G_1, H_5]$
F	$[G_4, H_5, K_5, L_5]$
G	

Total to stop at g

output : A, B, D, E, C, F, G
